

ASSIGNMENT 3

PROGRAMMING TECHNIQUE I (SCSJ 1013)

INSTRUCTIONS TO THE STUDENTS:

- *This assignment must be done **in pairs** (you can choose your own partner).*
- *Your programs must follow the input and output as required in the text and shown in the examples. You must test the programs with (but not limited to) all the input given in the examples.*
- *Any form of plagiarisms is **NOT ALLOWED**. Students who copied other student's program/assignment will get **ZERO** mark (both parties, student who copied and student that share their work).*
- *Please insert your **name, IC Number, section of your class and date** as a comment in your program.*

SUBMISSION PROCEDURE:

- *Only one submission per pairs (partners) that includes 2 files are required for the submission which is the source code (the file with the extension .cpp) and the input file (the file with the extension .txt).*
- *Submit the assignment via the UTM's e-learning system.*

QUESTION

Ministry of Transport Malaysia is required to prepare a report of the total road accidents by states in Malaysia from the year, 2006 to 2015.

Instructions:

Write a C++ program to calculate the average number of road accidents for each state and find the highest number of road accidents from 2006 to 2015. Your program should be able to do the following tasks:

- (a) The program should use the following **struct** definition:

```
struct dataAcc
{
    int numAcc[10]; //number of road accidents from 2006-2015
    string state; //states in Malaysia
    float avg; //average number of road accidents for 2006-2015
}
```

(b) The program should use an array of **struct** defined in (a) to store the total road accidents by states in Malaysia from 2006 to 2015.

(c) The program will read input data from an input file named “input1.txt” into the array of **struct** declared in (b). Example of input data in “input1.txt” is shown in **Figure 2**.

(d) The program should have two (2) global constants and one (1) global variable as follows:

Global constants:

NUM_STATE = 14 \Rightarrow Number of states

NUM_YEAR = 10 \Rightarrow Number of years

Global variable:

out \Rightarrow Variable to point to output file named “output.txt”

(e) Besides the function **main()**, the program has three (3) other functions as described in **Table 2**. One of the functions is given below:

```
void displayLine()
{
    for (int i = 0; i < 98; i++)
        out << "-";
    out << endl;
}
```

Based on the description given in **Table 2**, the program needs to define two (2) more functions. You should use appropriate argument(s) (if necessary) for each function.

Table 2: Description of functions

Function	Description
displayLine()	To display lines using 98 characters of ‘-’ in the output file using a loop.
cal_Avg()	To calculate the average number of road accidents for each state. The function should accept a 1D array of the number of road accidents for 10 years for each state as its argument. The function should return the average number of road accidents for each state.
find_HighLow()	To find and display the highest number of road accidents from 2006 to 2015. The function should accept a 1D array of structures as its argument.

(f) The program needs to display the following information. **Figure 3** shows the output of the successful program. You should use a proper output formatting.

- Name of state.
- Number of road accidents for 2006-2015 in each state.
- Average number of road accidents for 10 years in each state.
- The highest number of road accidents for 10 years with the name of state and year.
